摘要

乳房外柏哲氏症是一種罕見的上皮腫瘤，好發於男女之外生殖器及其附近之皮膚上，特別在男性之外生殖器上，至今只有少於 100 例被報告。皮膚切片及免疫組織化學分析提供了確切的診斷，而治療則以及膚廣泛切除合併植皮重建手術為主。我們在此報告一個病例並做文獻回顧。

Abstract

Extramammary Paget's disease (EMPD) is a rare intraepithelial adenocarcinoma which usually occurs at the vulva, perianal region, perineum, prepuce, and scrotum, especially around the male external genital area; to date no more than 100 cases have been reported world wide We report on a 60-year-old male patient that had suffered from intractable eczema-like skin lesions over the external genital area for 2 years and had received repeated topical steroidal prescriptions. EMPD was diagnosed by skin biopsy, and reconstructive surgery was performed using a medial thigh skin graft wide excision of the lesion. The skin grafts healed well, and there was no recurrent lesion detected after follow-up for 1 year. To diagnose such an easily overlooked epidermal malignancy, early biopsy for suspicious chronic lesions is highly recommended.
