摘要

Abstract

Many surgical or medical conservative treatments were developed to avoid castrating hysterectomy, so that the patient's fertility could be preserved. These procedures were often combined with intra-muscular, intra-arterial, or intra-amniotic methotrexate (MTX) administration. Regardless of the described treatment, the gestational ages of all reported cases were early at 12 weeks or fewer of gestation. We report a case of cervical pregnancy with the most advanced gestational age in the English literature up to now, which was successfully treated with conservative medical management.
