## Abstract:

Platelet-derived growth factor (PDGF) is important for alveogenesis of the normally developing lung. The aims of this study were to evaluate the effects of experimental oligohydramnios on lung growth, PDGF and its receptors expressions, and lung morphology in fetal rats. On day 16 of gestation, we anesthetized timed pregnant Sprague-Dawley dams, punctured the uterine wall and fetal membranes of each uterine sac, which resulted in oligohydramnios. Fetuses in the opposite uterine horn served as controls. On days 19 and 21 of gestation, the fetuses were delivered by cesarean section and weighed, and the lungs were dissected free and weighed. Radial saccular count was measured in fetal rat lungs delivered on day 21 of gestation. Oligohydramniotic rats exhibited significantly lower lung/body weight ratios on days 19 and 21 and significantly lower radial saccular counts on day 21 of gestation than did the control rats. Oligohydramnios significantly decreased PDGF-A and -B, and collagen I gene and protein expressions, and elastin content on days 19 and 21 of gestation, and significantly decreased PDGFR- $\alpha$  and - $\beta$  gene expressions on day 19 of gestation. These results suggest that decreased PDGF expressions may be important in the pathogenesis of lung hypoplasia induced by oligohydramnios.

Key words: lung growth, collagen, elastin

## 摘要

血小板生長因子對於正常發育肺臟肺泡的發展很重要。這項研究的目的是評估實驗性羊水過少對胎鼠的肺生長、肺形態學、血小板生長因子及其接受體的影響。在懷孕週數第 16 天，我們麻醉懷孕的大白鼠，刺穿子宮囊和胎鼠的膜，導致羊水過少。在另一角的子宮角裡的胚胎作為控制組。在懷孕週數第 19 天及第 21 天，以剖腹產手術取出胎鼠，秤出生體重，在取出肺、秤肺重。在懷孕週數第 21 天出生的胎鼠，測量其肺 Radial saccular count。與控制組老鼠比，羊水過少的老鼠在懷孕週數第 19 天及第 21 天時有比較低的肺/體重比率。羊水過少的老鼠在懷孕週數第 19 天及第 21 天時有比較低的血小板生長因子，collagen I 基因表現和蛋白質表現，elastin 基因表現。這些結果顯示血小板生長因子表現減少可能在羊水過少引起的肺發育不良的病理變化扮演重要的角色。

關鍵詞：肺生長、膠原蛋白、彈力蛋白

Pulmonary hypoplasia is common in the perinatal period and is a significant cause of death in newborn infants (1). Oligohydramnios is one of the most common associated abnormalities. Oligohydramnios may retard fetal lung growth and results in pulmonary hypoplasia in experimental animals (2, 3) and in human fetuses with prolonged rupture of the membrane (4) or renal anomalies with decreased fetal urine output (5). However, the exact mechanism by which oligohydramnios alters the fetal respiratory system remains unknown.

Platelet-derived growth factor (PDGF) is important for alveogenesis of the normally developing lung (6). PDGFs are homodimers or heterodimers consisting of two distinct polypeptide chains (A and B), which can be dimerized via sulfhydryl bridges to form three bioactive isoforms (AA, BB, and AB) (7). Physical forces play an important role in regulating fetal lung growth and maturation (8, 9). The main physical force the lung experiences is stretching produced by fetal breathing movements and lung fluid in the airspaces during normal lung development (10). In the fetus, the lungs are filled with a fluid that is secreted from the pulmonary epithelium into the potential airspaces and leaves the lungs via the trachea. The fluid maintains the lungs in an expanded state and provides the tissue with the mechanical stretching that is necessary for normal lung development (11). Mechanical stretching may increase growth factor expression through intracellular signal transduction pathways (12) and has significant impact on the synthesis and secretion of several extracellular matrix (ECM) molecules in fetal lung cell culture (13, 14). However, little is known about the effects of oligohydramnios on the lung PDGF and ECM status *in vivo*.

## **MATERIALS AND METHODS**

**Animals.** This study was approved by the Animal Care and Use Committee at Taipei Medical University and was performed with timed pregnant Sprague-Dawley rats. On day 16 of gestation, pregnant dams were anesthetized with pentobarbital (50 mg/kg, i.p.). An abdominal midline incision was made, and the two uterine horns were exposed and kept moist with phosphate-buffered saline. The uterine wall and fetal membranes of each uterine sac in one horn were punctured using a 19-gauge needle, which resulted in immediate visible leakage of amniotic fluid and a decrease in the size of the uterine sac. Fetuses in the opposite uterine horn served as controls. The uterus was returned to the abdomen and the abdominal incision was repaired. On days 19 and 21 of gestation, the fetuses were delivered by cesarean section and allowed not to breathe. The fetuses were weighed and killed by pentobarbital (100 mg/kg, i.p.); lungs were removed, dissected free, weighed, and values were expressed as the ratio (%) of lung/body weights.

**Reverse transcription PCR.** The left lung was ground into a powder in liquid nitrogen, and gene expressions were measured with RT-PCR. The PCRs were carried out with the primers shown in Table 1. At least five samples on each gestational day were analyzed for each gene in each group.

**Western blot analysis.** Proteins (30  $\mu$ g) were separated on SDS-PAGE under a non-reducing condition and electro-transferred to a polyvinylidene difluoride membrane (Immobilon<sup>P</sup>, Millipore, Bedford, MA, USA).

**Lung collagen and elastin content.** The Sircol collagen and Fastin elastin assay (Biocolor, Belfast, UK) was performed following the manufacturer's instructions and modified from Philips et al. (15).

**Statistical analysis.** Results are presented as the means  $\pm$  SEM. Comparisons between control and oligohydramnios groups at equivalent gestational age were made using unpaired Student's *t*-test. Differences were considered significant at  $p < 0.05$ .

## **RESULTS**

There were three and six pregnant dams used on days 19 and 21 of gestation, respectively. Control fetuses were all alive at the time of the cesarean section. Three of 26 (11.5%) and 30 of 53 (56.6%) oligohydramniotic fetuses were dead on days 19 and 21 of gestation, respectively.

**Body weight, lung weight, and the lung/body weight ratio (%).** Oligohydramniotic rats exhibited significantly lower lung/body weight ratios on day 19 of gestation and lower lung weights and lung/body weight ratios on day 21 of gestation when compared with control rats (Table 2).

**PDGF and PDGFR gene expressions.** Oligohydramnios significantly decreased PDGF-A -B, R- $\alpha$ , and -R- $\beta$  gene expressions on day 19 of gestation (Fig. 1A). On day 21 of gestation, oligohydramnios also decreased PDGF and PDGFR gene expressions and the values reached statistical significance for PDGF-A and -B only (Fig. 1B).

**Western blot analysis of PDGF.** PDGF-AA and -BB decreased in fetal lung tissue exposed to oligohydramnios on day 16 and harvested on days 19 (Fig. 2A) and 21 (Fig. 2B) of gestation.

**CTGF and collagen type I gene expressions.** In this study we measured only collagen type I gene expression because it constitutes greater than 65% of the total lung collagen. Oligohydramnios significantly decreased collagen I gene expressions on days 19 (Fig. 3A) and 21 (Fig. 3B) of gestation and had no significant effect on CTGF gene expressions.

**Lung collagen and elastin content.** Oligohydramnios significantly decreased lung collagen and elastin content when compared to the control rats on days 19 and 21 of gestation (Fig. 4).

## DISCUSSION

Oligohydramnios may retard fetal lung growth and result in pulmonary hypoplasia (2-5). Pulmonary hypoplasia was defined as a low lung weight for a given body weight. The reported effects of oligohydramnios during late gestation on lung morphometry have been inconsistent in rodents (16, 17). We found that oligohydramnios created on day 16 of gestation decreased lung/body weight ratio on days 19 and 21 of gestation and decreased the radial saccular count on day 21 of gestation. In our preliminary experiment, we found that pulmonary hypoplasia induced by oligohydramnios was not consistently found when we used a finer needle.

PDGF is a powerful stimulator of fibroblast chemotaxis, proliferation, and collagen production (18, 19). Han et al. reported that both PDGF and its receptors are present in fetal rat lung (20, 21). Buch et al. investigated the ontogeny of PDGF gene expression in fetal rat lung epithelial cells and found that PDGF-A gene expression declined with advancing gestation, whereas PDGF-B gene expression increased (22). The effects of oligohydramnios on PDGF gene expression in fetal lung tissues are not well characterized. By using antisense PDGF-A oligonucleotides and antisense PDGF-B oligodeoxynucleotides in embryonic rat lung explant culture, Souza et al. found that PDGF-AA and -BB play critical roles in early lung branching morphogenesis and lung growth, respectively (23, 24).

CTGF, a cysteine-rich, heparin-binding protein, has been implicated in fibroblast proliferation, cellular adhesion, angiogenesis, and ECM synthesis (26). In this study, we found decreased total collagen contents and comparable CTGF expressions on days 19 and 21 of gestation. PDGF is a powerful stimulator of fibroblast chemotaxis and collagen production (18, 19). PDGF overexpression produces fibrosing alveolitis in rats (27), and PDGF inhibition by receptor tyrosine kinase inhibitors attenuates radiation-induced pulmonary fibrosis in mice (28). Those and our findings suggest that CTGF is not a major factor regulating collagen production, and that PDGF plays a pivotal role in the pathogenesis of decreased collagen content in hypoplastic lung induced by oligohydramnios.

Two major stimuli to fetal lung growth result from stretching due either to 1) intermittent and repetitive fetal breathing movements, or 2) a constant distending pressure when fetal breathing movements are absent (10). The constant distending pressure is produced by the secretion of lung fluid and the resistance to outflow in the upper airway (29). Oligohydramnios does not influence fetal breathing movements but it does decrease the volume of fluid within the potential airways and airspaces (3, 30). The fluid maintains the lungs in an expanded state and provides mechanical stretching for the tissue that is necessary

for normal lung development (11). Mechanical stretching increases growth factors expressions through intracellular signal transduction pathways (12).

In conclusion, the results of this study showed that maternal oligohydramnios during late gestation decreased PDGF and its receptor expressions, decreased total collagen and elastin contents, and arrested lung development in fetal rat lungs. These results suggest that PDGF expressions may be important in the pathogenesis of oligohydramnios-induced lung hypoplasia. The underlying mechanism is unclear, and its elucidation may provide useful therapeutic strategies for pulmonary hypoplasia induced by oligohydramnios.
