中文摘要

背景: 非典型抗精神病藥物對於精神分裂症之治療具有良好之療效，因此被視為是治療精神分裂症的第一線藥物。但是近來由於可能會有增加罹患糖尿病或其他新陳代謝異常之風險而受到注意。本研究將針對 olanzapine 及 risperidone 對於精神分裂症患者之胰島細胞所出現之急性的反應進行研究。

方法: 參與研究之精神分裂症患者將分成兩組，一組接受每天 10 毫克之 olanzapine 藥物治療，另一組則接受每天 2 毫克之 risperidone 藥物治療，研究期間為 14 天。個案將在第 0 天及第 14 天利用 intravenous glucose tolerance test 方式來檢查胰島素分泌及反應，並檢驗空腹血糖、胰島素、血脂肪、及 leptin 濃度。

結果: 兩組個案在研究開始時的各項基本資料及實驗室數值均無明顯差異。在兩週的治療後，兩組在治療前後之體重、BMI、空腹血糖、胰島素、膽固醇、及 leptin 濃度亦無明顯差異。olanzapine 藥物治療組則在 triglyceride 濃度出現顯著增加。在兩週的治療後，兩組在治療前後之胰島素敏感性及阻抗性均無顯著差異。olanzapine 藥物治療組則在胰島素分泌出現顯著減少。

結論: 在接受兩周之 olanzapine 治療後，精神分裂症患者會出現胰島素分泌減少之情形，顯示 olanzapine 可能會對於胰島細胞功能有直接之影響。

關鍵字: 非典型抗精神病藥物，精神分裂症，olanzapine，risperidone，胰島素分泌。

Abstract

Background: Atypical antipsychotics, such as risperidone, olanzapine, and quetiapine, are effective treatment for schizophrenia and considered as first line therapy. Recently, increasing attention has been drawn to the potential diabetogenic effect of novel antipsychotics. The goal of this prospective study is to evaluate the acute effect of olanzapine and risperidone treatment on pancreatic β -cell function in atypicals-naïve schizophrenic patients.

Methods: Subjects were assigned to therapy with olanzapine (10 mg/day; n=13) or risperidone (2 mg/day; n=13) for 14 days. The metabolic parameters were quantitatively assessed at baseline and the end of study period by using the intravenous glucose tolerance test. The levels of fasting glucose, fasting insulin, cholesterol, triglyceride, high-density lipoprotein, low-density lipoprotein, and leptin were also assessed.

Results: There were no significant within-group changes in weight or body mass index for both groups after 2 weeks treatment. The levels of fasting glucose, fasting insulin, cholesterol, or leptin did not change in both groups. The triglyceride level significantly increased in olanzapine group. Insulin sensitivity index and insulin resistance (insulin/glucose ration and homeostasis model assessment) did not change in both groups. Insulin secretion significantly decreased in olanzapine group.

Conclusions: After 2-weeks of olanzapine treatment, schizophrenic patients decreased insulin secretory response to a hyperglycemic challenge. The results of this study support the hypothesis that olanzapine directly impair pancreatic β -cell function.

Keywords: atypical antipsychotics, schizophrenia, olanzapine, risperidone, insulin secretion.

報告內容

The atypical antipsychotics, such as olanzapine, risperidone, quetiapine, and ziprasidone, are effective in eliciting both the positive and negative symptoms in schizophrenia (Emsley and Oosthuizen 2003; Kelleher et al 2002; Mortimer 2003). Compared with traditional antipsychotics, atypical antipsychotics cause a lower incidence of extrapyramidal symptoms and minimal perturbation of prolactin levels. These advantages have led to an increasing use of atypical antipsychotics as the first line therapy for schizophrenia. The atypical antipsychotics act as antagonists at multiple receptors, including members of the dopaminergic, serotonergic, adrenergic, muscarinic, and histaminergic families (Tandon et al 1999). Although the precise mechanism of action remains uncertain, the relatively high affinity for serotonergic receptors and the relatively low dopaminergic D₂ activity are believed to contribute to the improved efficacy and increased tolerability of atypical antipsychotics (Reynolds 2004).

Compared with the general population, life expectancy in schizophrenic patients is shorter by as much as 20%, attributable to higher rates of suicide, accidental deaths, and natural causes such as cardiovascular disease (Goff et al 2005; Harris and Barraclough 1998; Simpson and Tsuang 1996). Recently, atypical antipsychotics have been linked to several forms of morbidity, including obesity, hyperlipidemia, and type 2 diabetes mellitus (Bergman and Ader 2005; Jin et al 2004; Melkersson and Dahl 2004; Newcomer 2004; Wirshing 2004). While metabolic abnormalities induced by atypical antipsychotics have been frequently reported, the mechanisms responsible for such an association remain unclear.

Evidence linking atypical antipsychotics to metabolic dysregulation is largely based on case reports and retrospective analyses, which note a disproportionately greater number of patients developing fasting hyperglycemia and new-onset diabetes after the initiation of atypical antipsychotic treatment (Bergman and Ader 2005; Haupt DW and Newcomer 2001; Henderson et al 2000; Jin et al 2004; Koro et al 2002). Although methodological issues related to nonrandom prescribing patterns and insensitive or non-uniform ascertainment of hyperglycemia or diabetes make these results difficult to interpret, clozapine and olanzapine have been most strongly implicated in pharmacoepidemiological studies. Sowell et al. (Sowell et al 2002) studied insulin secretion using hyperglycemic clamp technique in normal subjects after 15-17 days treatment of olanzapine, risperidone, or placebo. There was a significant change in insulin sensitivity in the olanzapine group and not the risperidone group. The authors ascribed this change to weight gain, based on regression analysis (Sowell et al 2002). In another prospective randomized study in healthy volunteers, the authors found no significant changes in insulin sensitivity or insulin secretion after 3 weeks of treatment with olanzapine or risperidone (Sowell et al 2003). However, their subjects were a normal population instead of patients with schizophrenia. Accordingly, first-episode, drug-naïve patients with schizophrenia have impaired fasting glucose tolerance and are more insulin resistant and have higher levels of plasma glucose, insulin, and cortisol than healthy comparison subjects (Ryan et al 2003). Recently, Henderson et al. (Henderson et al 2005) evaluated the glucose metabolism in antipsychotics-treated schizophrenic patients using a frequently sampled intravenous glucose tolerance test. They found that both non-obese clozapine- and olanzapine-treated groups displayed significant insulin resistance and impairment of glucose effectiveness compared with risperidone-treated subjects (Henderson et al 2005). Since drug

treatment was not randomized and assessment was cross-sectional, the finding of an association between clozapine and olanzapine and impairment of glucose metabolism cannot be conclusively established as a causal relationship.

While the incidence of new-onset diabetes appears to be increasing in schizophrenic patients treated with certain atypical antipsychotics, it remains unclear whether atypical antipsychotics are directly affecting glucose metabolism or simply increasing known risk factors for diabetes, such as obesity, lipid abnormalities, and decreased physical activity secondary to sedative effects (Henderson 2002). Identification of mechanisms contributing to putative increased risk of diabetes with atypical agents may help to explain apparent inconsistencies in results between pharmacoepidemiological studies and allow identification of patients at risk.

Although treatment with many psychotropic medications may be temporally associated with weight gain, reports of severe hyperglycemia with ketoacidosis in the absence of weight gain or shortly after initiation of treatment have led to speculation that some of the atypical antipsychotics may have a rapid and direct effect that impairs insulin secretion or insulin action (Baptista et al 2002; Henderson 2002; Mir and Taylor 2001). A number of hypothetical mechanisms for such an effect have been postulated based on the receptor binding profiles of the medications, including drug-related decreases in insulin secretion or insulin sensitivity (Baptista et al 2002; Jin et al 2004).

The objective of this prospective study was to test whether atypicals-naïve schizophrenic subjects treated with olanzapine or risperidone experienced decreased insulin secretion, as assessed by intravenous glucose tolerance test (IVGTT). The IVGTT is a well-established method for assessing glucose metabolism and has been widely used in the medical fields of diabetes and obesity research. A prospective randomized design in atypicals-naïve schizophrenic patients was chosen to allow comparison of the differences between risperidone- and olanzapine-treated groups.

Methods and Materials

Study Subjects

The facility's institutional review board approved this prospective, randomized, open-label study. After providing a description of the study to the patients, written informed consent was obtained. Subjects were male or female between 18-60 years of age, with body mass index (BMI) between 20-27 kg/m², fasting glucose level of 110 mg/dl or less, and no personal or family history of diabetes. Research psychiatrists evaluated patients after a thorough medical and neurological workup. The Structured Clinical Interview for DSM-IV (American Psychiatric Association 1994) was conducted for the diagnosis. All enrolled patients fulfilled the DSM-IV diagnosis of schizophrenia. None were receiving atypical antipsychotics prior to this study. None of the patients had been pretreated with depot antipsychotics during at least 6 months before study entry. Patients with Axis I diagnosis other than schizophrenia or medical or neurological illness were excluded. Subjects were excluded for medical conditions that could confound metabolic assessments. Medications (e.g., lithium, carbamazepine, valproic acid, propranolol, tricyclic antidepressants, or other SSRIs) that may influence body weight, glucose/lipid metabolism, or drug disposition were not allowed (Zimmermann et al 2003).

Study Design

Screening studies, physical examination, and laboratory tests were administered, and medical history was collected to determine eligibility for study enrollment. A total of 26 inpatients were included into this study and were randomized into two treatment groups: olanzapine therapy (10 mg/day) and risperidone therapy (2 mg/day). Glucose metabolism was studied using intravenous glucose tolerance tests. Before the baseline IVGTT, subjects were admitted to an inpatient facility for diet stabilization with an isocaloric diet (25-35 kcal/kg). The tests were performed in the morning after an overnight fast both before and 2 weeks after the start of atypical antipsychotics. Glucose (0.5 g/kg body weight) was administered intravenously. Blood samples for measurement of glucose and insulin were taken from the opposite arm at $t = -15, 0, 5, 10, 15, 20, 30, 40, 50,$ and 60 minutes. The glucose disappearance rate (k_G) was calculated by linear regression from the log-transformed glucose values of $t = 10$ to 30 minutes. A k_G value below 0.8 mmol/L per minute was considered as abnormal, between 0.8 and 1.2 mmol/L per minute as indeterminate, and above 1.2 mmol/L per minute as normal (Bergman RN 1985; Elmer et al 1994).

Insulin secretion, the secretion response to a glucose load, was calculated as area under the curve using a linear trapezoidal technique from the serum value at each time point after subtraction of the $t = 0$ value (increment). Insulin resistance was calculated using the insulin/glucose ratio, homeostasis model assessment (HOMA-R: fasting glucose [mmol/L] * fasting insulin [mU/L] /22.5), and quantitative insulin sensitivity check index (QUICKI: $1/[\log(\text{fasting insulin}) + \log(\text{fasting glucose})]$) (Avignon et al 1999; Katz et al 2000; Matthews et al 1985).

Laboratory Assay

Laboratory assays were performed by the chemistry laboratory of Taipei Institute of Pathology. The serum levels of glucose, triglyceride, cholesterol, low-density lipoprotein (LDL), high-density lipoprotein (HDL) were measured by using the Olympus AU400 chemistry analyzer. The plasma glucose level was measured with a hexokinase method. The plasma levels of triglyceride and cholesterol were measured with enzymatic colorimetric method. Plasma HDL level was determined by homogeneous liquid selective detergent. Plasma low-density lipoprotein-cholesterol was calculated from the Friedewald equation (Friedewald et al 1972). Plasma insulin and leptin were determined using the radioimmunoassay kit and quantified using a Packard Cobra Quantum Gamma Counter.

Statistical Methods

Descriptive statistics are represented as mean \pm SD. The Kolmogorov-Smirnov testing revealed a trend toward normality of distribution for the variables. Subgroups were compared using t-test for continuous variables and chi-square test for categorical variables. A p-value of less than 0.05 was considered to have statistical significance.

Results

Twenty-six subjects signed informed consents and entered the study. Overall, the procedure was well tolerated, and all subjects were able to complete all aspects of the study.

For the entire sample, the mean \pm SD age was 37.3 ± 8.3 years. All subjects were Taiwanese and 18 (69%) were male. The two treatment groups did not differ in age, sex, BMI, weight, or duration of illness or medication treatment.

Baseline Assessment

There were no significant between-treatment group differences in the baseline levels of glucose, insulin, total cholesterol, triglyceride, HDL, LDL, and leptin.

Glucose Metabolism and Lipid

Intravenous glucose tolerance test was performed at baseline and after 14 days of antipsychotics treatment. In the risperidone group, weight, BMI, fasting glucose, fasting insulin, triglyceride, total cholesterol, HDL, LDL, and leptin did not change significantly at the end point. Insulin resistance, calculated by the HOMA-R and insulin/glucose ratio, remained similar after 2-week risperidone treatment. Insulin sensitivity index and insulin secretion also remained the same in the risperidone group.

In the olanzapine group, weight, BMI, fasting glucose, fasting insulin, total cholesterol, HDL, LDL, and leptin did not change significantly at the end point. The triglyceride level increased significantly from baseline to end point in olanzapine group. The insulin sensitivity index and insulin resistance remained the same after 2-week olanzapine treatment. In response to a glucose load, the insulin secretion decreased significantly in the olanzapine group.

The weight, BMI, fasting glucose, fasting insulin, triglyceride, total cholesterol, HDL, LDL, and leptin did not differ significantly between groups at the end of study. Although there was no significant difference between groups for insulin sensitivity index or insulin resistance, there was a significant group difference in insulin secretion ($p=0.04$).

Discussion

In this first prospective study to evaluate glucose metabolism in atypical-naïve schizophrenic patients after 2 weeks of atypical antipsychotics administration, we investigated the different effect of olanzapine or risperidone treatment on pancreatic β -cell function. The insulin secretion decreased significantly in patients treated with olanzapine, but not risperidone.

Accumulating clinical evidence indicates that the atypical antipsychotics olanzapine and clozapine have an increased risk of triggering hyperglycemic events in schizophrenic patients (Haupt DW and Newcomer 2001; Lindenmayer et al 2001), which can occur independently of the weight gain associated with these compounds (Koller and Doraiswamy 2002; Ramankutty 2002). The level of hyperglycemia is often severe and can be attributed to drug treatment, as cessation of use often leads to a full or partial reversal of the hyperglycemia (Koller and Doraiswamy 2002; Ragucci and Wells 2001). While it is accepted that these atypical antipsychotics harbor an increased risk of disruption glucose regulation, the pharmacological basis for the differences in diabetic liability that exists within the antipsychotics class is not known. Of the commonly used atypical antipsychotics, clozapine and olanzapine appear to have the greatest diabetogenic effect (Bergman and Ader 2005; Jin et al 2004).

The presence of a significant decrease in insulin secretion during olanzapine treatment is in contrast to results reported by previous studies. Previous studies performed with schizophrenic

patients have shown elevated fasting blood glucose concentrations together with hyperinsulinemia and body weight gain after active olanzapine treatment (Newcomer 2005). However, the design of these studies is not comparable to ours. Some previous studies applied retrospective or cross-sectional designs that could not establish a causal relationship between olanzapine treatment and metabolic disturbances (Henderson et al 2005; Osser et al 1999). Other studies used healthy volunteers, animals, or culture cells as study subjects that could not reflect the real situation of schizophrenic patients (Ader et al 2005; Melkersson et al 2001; Robinson et al 2005; Sowell et al 2003; Sowell et al 2002). Our study applied the prospective design to evaluate the effect of olanzapine and risperidone on glucose homeostasis in atypicals-naïve schizophrenic patients. The results of this study suggest that olanzapine has an acute and direct effect that impairs insulin secretion.

Mechanisms postulated to account for antipsychotics-induced metabolic disturbances include primary damage to the pancreatic islet cells and/or sympathetic nervous system dysfunction, and a secondary phenomenon related to weight gain and insulin resistance (Goldstein et al 1999). Some cases of olanzapine-induced pancreatitis have been published since 2000 (Doucette et al 2000; Hagger et al 2000; Waage et al 2004). In this study, the olanzapine-induced decrease in insulin secretion might be related to direct damage of pancreatic cells. The regulation of insulin secretion from pancreatic β -cells is a complex physiological process controlled by a number of interacting signaling components (Chey and Chang 2001). In a placebo-controlled study of olanzapine and risperidone in dogs, olanzapine resulted in marked hepatic insulin resistance and impairment in the compensatory upregulation of β -cell sensitivity to glucose (Ader et al 2005). Recently, Johnson et al explored how antipsychotics impact both fuel and neurohumorally mediated insulin secretion from isolated perfused rat islets (Johnson et al 2005). Their results suggest that inhibition of cholinergic-stimulated insulin secretion is a possible contributing factor in the disruption of glucose homeostasis by olanzapine. Besides the antimuscarinic properties, it is clear that additional mechanisms contribute to the increased diabetic liability of olanzapine. Another mechanism that may work in synergy with muscarinic antagonist activity is 5-HT_{2A} receptor antagonism. It has been demonstrated that specific 5-HT_{2A} agonists can rapidly stimulate glucose uptake in skeletal muscle by a mechanism which does not depend upon components that participate in the insulin signaling pathway (Hajduch et al 1999).

In our present study, triglyceride levels were higher in the olanzapine group compared with the risperidone group. Elevated triglyceride concentrations have also been observed in olanzapine-treated patients (Osser et al 1999). In this study, olanzapine-induced increases in triglyceride levels occurred prior to the weight gain and other lipid levels changes. Multiple studies of atypical antipsychotics have not found a strong association between the increases in serum triglyceride levels and weight gain (Meyer 2001) and proposed the possibility of a direct effect on lipid levels by some as yet unknown mechanism (Newcomer 2005).

Two limitations of the current study warrant specific comment. First, schizophrenic subjects without exposure of atypical antipsychotics were enrolled in this study. As the prevalence of diabetes in schizophrenic patients appears to exceed that in the general population (Dixon et al 2000; Goff et al 2005), it could be argued that schizophrenic subjects possess higher susceptibility to pancreatic β -cell dysfunction during treatment with antipsychotics. The study subjects had previous exposure of typical antipsychotics for 8.5 ± 4.9 years. The cumulative

effect of type and length of typical antipsychotic treatment might play a role in the development of pancreatic dysfunction (Arranz et al 2004). Another potential limitation is the relatively short duration of drug exposure employed in the study. The main objective of this study was to evaluate the potential acute direct effect of olanzapine or risperidone on insulin secretion. There were several studies reported that changes in glucose metabolism might occur within 1-2 weeks of atypical antipsychotic treatment (Chae and Kang 2001; Sowell et al 2002). Therefore, we believed that 2 weeks would provide adequate exposure, particularly with the use of highly sensitive intravenous glucose tolerance test. The results of the current study cannot address potential effects of olanzapine or risperidone after long-term treatment or with higher doses of these medications.

In summary, atypicals-naïve schizophrenic subjects treated with olanzapine or risperidone for 2 weeks exhibited different changes in insulin secretion. In olanzapine treated subjects, the changes of insulin secretion happen prior to the changes of body weight and insulin sensitivity. Overall, the results of our study support the hypothesis that olanzapine has an acute and direct effect to decrease insulin secretion.

Table 1. Metabolic Profiles of Patients treated with Olanzapine or Risperidone

	Olanzapine		Risperidone	
	Baseline	2-week	Baseline	2-week
Body Weight (kg)	69.1 ± 9.4	69.7 ± 9.6	68.4 ± 10.1	69.2 ± 9.5
BMI	25.8 ± 4.1	26.1 ± 4.2	25.6 ± 4.3	25.9 ± 4.1
Fasting Glucose (mg/dL)	92.6 ± 10.3	91.5 ± 9.7	100.3 ± 16.4	92.7 ± 10.3
Fasting Insulin (mU/L)	14.2 ± 9.6	13.0 ± 7.9	12.4 ± 7.9	13.3 ± 9.6
Triglyceride* (mg/dL)	121.5 ± 79.9	154.9 ± 113.7	112.5 ± 90.9	120.5 ± 78.5
Total Cholesterol (mg/dL)	157.2 ± 25.3	166.6 ± 27.2	161.2 ± 24.2	159.2 ± 24.7
HDL:	41.9 ± 13.9	39.7 ± 13.2	46.8 ± 13.1	42.3 ± 14.4
LDL	92.1 ± 19.3	95.7 ± 22.9	96.9 ± 20.4	91.8 ± 19.5
Leptin	9.6 ± 6.2	10.9 ± 7.4	9.2 ± 6.9	9.5 ± 6.4
Insulin Secretion* (mU*min/L)	4453.3 ± 805.4	2771.8 ± 440.2	3791.7 ± 707.7	4646.5 ± 825.4
HOMA-R (mmol*mU/L)	3.31 ± 2.22	2.96 ± 1.78	3.14 ± 2.34	3.30 ± 2.12
Insulin/Glucose Ratio (mU/mmol)	2.76 ± 1.95	2.57 ± 1.65	2.16 ± 1.29	2.67 ± 1.94
QUICKI	0.34 ± 0.04	0.33 ± 0.03	0.34 ± 0.04	0.34 ± 0.05
Insulin Sensitivity Index (KG) (mmol/L per min)	1.46 ± 0.34	1.52 ± 0.37	1.43 ± 0.40	1.45 ± 0.32

* p < 0.05 within group comparison.

計畫成果自評

1. 本研究由於實驗設計較為煩瑣，參與研究之受試者需要接受密集之抽血檢驗，導致收案速度較預期緩慢，因此申請延長研究計畫執行期間。
2. 本研究所獲得之初步結果符合原本之預期，同時亦具有相當之學術價值，適合將結果發表於國際學術期刊中。目前已有論文發表 Chiu CC, Chen KP, Liu HC, **Lu ML***. The early effect of olanzapine and risperidone on insulin secretion in atypicals-naïve schizophrenic patients. **Journal of Clinical Psychopharmacology** 2006; 26:504-507 [SCI]
[*correspondence author]
3. 目前針對所獲得之初步成果進行更大樣本及較長追蹤時間之研究，並針對可能之作用機制設計出可行之預防及治療策略，此一研究將可以在研究上及臨床治療上帶來助益。
