摘要

Abstract

A 69-year-old man without any significant past medical history presented with turbid urine and dysuria for 2 weeks. He had no fever, poor appetite, body weight loss, diaphoresis, flank pain, or gross hematuria. Urinalysis in our hospital showed pyuria (>100/HPF) with microscopic hematuria (25 – 30/HPF). The urine culture was negative.

Physical examination was unremarkable. His blood pressure was 130/80 mm Hg. Chest film revealed no abnormality. His renal function was normal (serum creatinine: 1.0 mg dl⁻¹; urea nitrogen: 12 mg dl⁻¹). Plain film of his abdomen (Figure 1), renal ultrasonography (Figure 2), and an abdominal non-contrast computed tomography (CT) scan (Figure 3) were also performed for further workup.
